

→ Design a DS based on trie that allows adding and searching for new words

○ void (str word)

○ bool search (str word)

↳ word may contain dots
(.) where dots can be
matched with any letter

→ if a dot is found you have
to interact with all children
of current root until you find
a valid use case.

↳ Do DFS

↳ you might have
to check all
children of curr.
root

→ if Char is dot (.), list all keys for current children and create an interaction

↳ inside this interaction apply recursion call to the search method.

→ we will have at most 2 dots on the word, placed anywhere on it.

→ i need to pass the remaining of the word to the recursion

if (.) is found

↳ i get all children from current and pass a parameter for inner search

→ inner search does the word looping interaction for every children node

→ if, i find (.) i need to pass to inner search only the children from current root, because (.) state that current root value doesn't matter.
